The information I'm storing are account names and passwords. I know there is the ability to read from a BerkeleyDB (which I've used before) but I'm a little worried about scanning through my sensitive data. I'm concerned about being able to detect a shift in data, in the event of some kind of power/memory failure. Is it a good idea to just read the data in once, and scan every ten seconds for all the accounts in my application? I suspect this is the best and most safe approach. A: So what can go wrong if you use only once? A power failure is no problem at all, but if you store, say, an encrypted version of the data, you might get an encrypted copy without the decrypted information. Actually, that can be a problem already if the encrypted copy is stored in the same machine that has the decryption keys, and the service that encrypted the data is down. Power failure can happen fast. So your solution might be OK in practice, if you assume your application stores the data in a persistent store. In practice, you always have the problem that this store is somewhere in the middle between application machine and a database machine. So any power failure can mean that your data are gone. A hardware fault can kill your application and/or the other application can be stopped. These can be catastrophic as the other application is the one that is supposed to do the encryption/decryption. Most importantly, you should take into account that your application can be attacked from the outside. If your database is running on the same machine as your application is, then you should make it more resistant to such attacks. You should not do that with just a database (if you do, you are doing something wrong). The database itself has also attack vectors such as SQL injection. You don't say what access control policy you want to have, but if you want to be able to access all information even c6a93da74d
